#### Tree based methods I

### Regression tree example

STAT 32950-24620

Spring 2023 (5/16)

1/24

#### Tree based methods

- Regression Tree for estimating a continuous response variable
  - Take an average as the prediction in each partition region.
- Classification Tree for classifying a categorical response var.
  - Take a vote as the prediction in each partition region.
- Partition of the explanatory variable space is obtained by splitting the range of one predictor at a time.
- The partition regions are rectangles or hyper-rectangles.

## Tree based methods

- Supervised learning, with explanatory variables and a response variable.
- Find a partition of the space of explanatory variables (predictors, features).
- Provide a constant prediction in each partition region.

2 / 24

#### Regression Tree

**Regression Tree**: the response variable is continuous.

(vs Classification Tree: the response variable is categorical)

```
# libraries for Regression Tree
library(MASS)
library(tree) # earlier than "rpart" package
library(rpart) # alternative to "tree" package
library(rpart.plot) # nicer tree plots
```

rpart — Recursive Partitioning And Regression Trees

#### Data Example

#### Boston housing data

n = 506 observations, p = 13 input variables.

Response variable:

medv: median value of owner-occupied homes in USD 1000's

5/24

- lstat:

### Check data format

```
str(Boston); #summary(Boston)
```

```
## 'data.frame':
                   506 obs. of 14 variables:
   $ crim

```

### Example data: Explanatory variables

6 / 24

#### Regression Tree on the training data

percentage of lower status of the population

For this dataset, we plit the data into two equal sizes, create training and testing data.

```
set.seed(1)
# random sample from row numbers
train = sample(1:nrow(Boston), nrow(Boston)/2)
```

Fit a regression tree on the training data:

```
tree.boston=tree(medv~.,Boston,subset=train)
```

#### Check the fitted tree

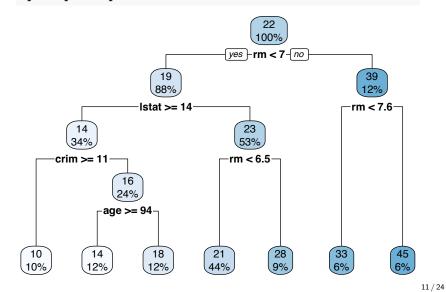

#### summary(tree.boston)

```
##
## Regression tree:
## tree(formula = medv ~ ., data = Boston, subset = train)
## Variables actually used in tree construction:
## [1] "rm" "lstat" "crim" "age"
## Number of terminal nodes: 7
## Residual mean deviance: 10.4 = 2550 / 246
## Distribution of residuals:
## Min. 1st Qu. Median Mean 3rd Qu. Max.
## -10.200 -1.780 -0.177 0.000 1.920 16.600
```

9 / 24

# Plot the regression tree (using rpart)

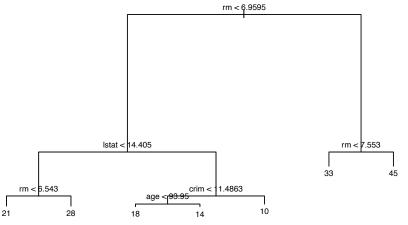

rpart.plot(rpart(medv~.,Boston,subset=train))

## Plot the fitted regression tree (using tree)

plot(tree.boston)
text(tree.boston,cex=0.7,digits=2)

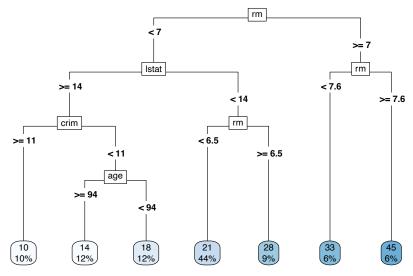

rm < 6.9595</pre>

10 / 24

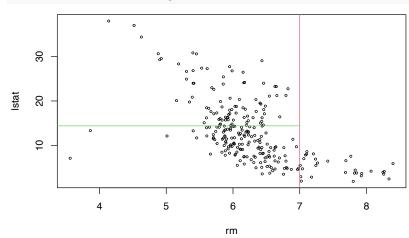

#### Plot the tree in another style (using rpart)

rpart.plot(rpart(medv~.,Boston,subset=train),type=5)

## Feature space stratification: Step 1 of the split

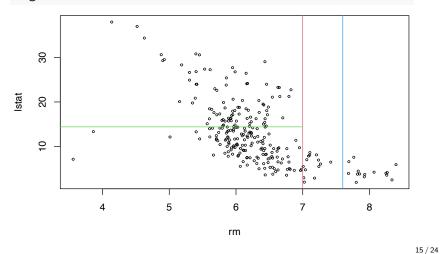

### Feature space stratification: Steps 2

14 / 24

## Feature space stratification: Steps 3

13 / 24

# How to built a regression tree

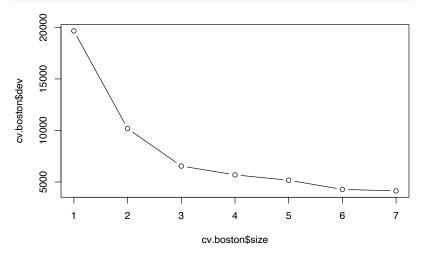

- Grow the tree upside down from the root to leaves.
- Start with a single region  $R_k$ , iterate.
  - Select a region  $R_k$ , a predictor  $X_j$ , a splitting point s, such that splitting  $R_k$  with the rule  $X_i < s$  optimally reduce RSS

$$\sum_{m=1}^{|T|} \sum_{x_i \in R_m} (y_i - \bar{y}_{R_m})^2$$

- Redefine the regions with the additional split.
- Iterate.
- $\bullet$  Terminate when there are very few observations (e.g.  $\leq$  5) in a region.

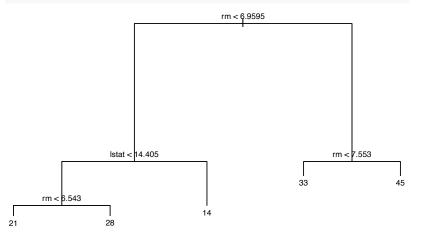

#### Tree deviance vs tree size

```
cv.boston=cv.tree(tree.boston)
plot(cv.boston$size,cv.boston$dev,type='b')
```

## Prune tree using deviance (5 regions)

plot(prune.tree(tree.boston,best =5)) # use best=tree-size
text(prune.tree(tree.boston,best =5),cex=0.7,digits =2)

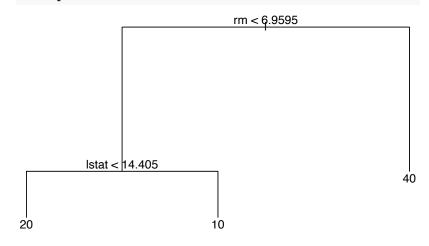

18 / 24

# Prune tree using deviance (3 regions)

17 / 24

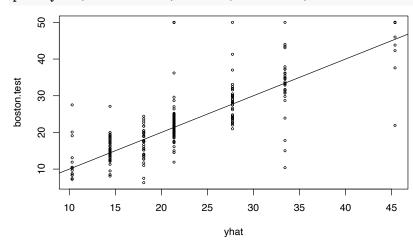

19 / 24

```
plot(prune.tree(tree.boston,best =3))
text(prune.tree(tree.boston,best =3))
```

# Tree fit

yhat=predict(tree.boston,newdata=Boston[-train,])
boston.test=Boston[-train,"medv"]
plot(yhat,boston.test,cex=.5); abline(0,1)

### Linear regression fit

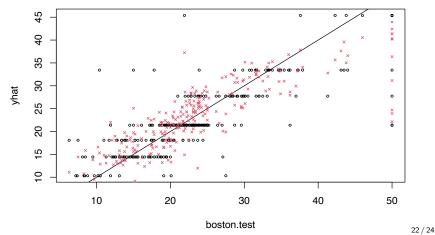

40

21 / 24

23 / 24

# Comparison of prediction of tree vs $\mbox{Im}$

yhat=predict(tree.boston,newdata=Boston[-train,])
boston.test=Boston[-train,"medv"]
plot(boston.test,yhat,cex=.5); abline(0,1)
points(Boston[-train,"medv"],yhatReg,cex=.5,pch=4,col=2)

#### Comparison of mean SS Residuals of tree vs Im

yhatReg

30

```
mean((yhat-boston.test)^2)
## [1] 35.29
mean((yhatReg-boston.test)^2)
```

## [1] 26.86

Which method is better?

Note: comparison of mean SS residual of training and testing data.

#### Cross validation

- Split the training data into 10 folds (default)
- For  $k=1,\cdots,10$ , using every fold except the kth
- Construct trees  $T_1, \dots, T_m$  for a range of  $\alpha$  in

$$\min_{T} \left( \sum_{m=1}^{|T|} \sum_{x_i \in R_m} (y_i - \bar{y}_{R_m})^2 + \alpha |T| \right)$$

#### Cost complexity pruning

For each tree T<sub>i</sub>, calculate RSS on the test set
 Remove the Weakest link, the subtree minimizes

$$\frac{RSS(T_1) - RSS(T_0)}{|T_0| - |T_1|}$$

 $\bullet$  Select  $\alpha$  that minimizes the average testing error.
